Abstract

Excessive fat in modern broiler strains is one of the major problems faced by the broiler industry. This experiment was conducted to study the effect of feed restriction at early age on broiler chicken performance, meat quality, abdominal fat content, and serum lipid profile. Two hundred, Cobb500 day-old broiler chicks were randomly assigned into five treatments; T1: *ad-libitum* feeding (control), T2 and T3: 75 and 50% of *ad-libitum* feeding from day 8 - 14, respectively, T4 and T5: 75 and 50% of *ad-libitum* feeding from day 15 - 21, respectively. All birds were fed with *ad-libitum* before and after the completion of the respective restriction periods. Total feed intake was significantly lower ($p < 0.05$) in T3 and T5 compared to the birds in the control group. However, no differences ($p > 0.05$) were observed in weight gain, feed conversion ratio, and dressing percentage among the treatments. Abdominal fat and muscle crude fat contents in birds fed with restricted diets from day 8 - 14 were significantly lower ($p < 0.05$) compared to the control. There was no influence ($p > 0.05$) of treatments on organ weights, muscle protein contents, and serum lipid profile. In conclusion, 50% feed restriction during day 8 - 14 is a better solution to reduce the fat deposition without interfering on growth performances of broiler chicken with lower cost.

Key words: Abdominal fat, Carcass quality, Feeding, Lipid, Profit

Introduction

In past, the main goal of the broiler producers was to increase the growth rate of broiler chickens for obtaining economic benefits within a short time [Peng *et al.*, 2016]. As a result, modern broiler strains show a fast growth rate. Unfortunately, the increase of growth rate is associated with high body fat deposition and mortality, incidences of skeletal disorders and metabolic diseases which directly lead to remarkable economic losses [Tumov & Teimouri, 2010]. The excessive amount of non-carcass fat deposition at the market age of bird is a common problem faced by the broiler farmers. The excessive fat reduces the carcass yield and consumer acceptance. It is also considered as a waste product that consumes the dietary energy [Shahin & El Azeem, 2006].

Meat, especially the red meat is classified as a food with high contents of cholesterol, fat, saturated fatty acids and low levels of unsaturated fatty acids [Shahin & El Azeem, 2006]. Normally, poultry meat contains a lower amount of saturated fatty acids and a higher amount of polyunsaturated fatty acids than the lean meat of mammals

[Cristina, 2009]. However, present strains of broilers contain 15 - 20% body fat, of which more than 85% is not physiologically required for body functions [Choct *et al.*, 2005]. Fats in the ready-to-cook bird cause to appear a fatty image to poultry meat. Intake of saturated fat in the human diet has been reported to increase blood cholesterol level and the incidence of coronary heart diseases, atherosclerosis, and cancer [Popova *et al.*, 2016]. Therefore, excessive fat deposition is an unfavorable trait from the view of both meat producers and consumers. Not only urban areas but also in rural households, consumers try to find low-fat, low-calorie, high-protein, cheap broiler meat [Prabakaran, 2003].

Because of economic concerns and consumer objections to excess fat deposition, feeding strategies to reduce the body fat content in the broiler carcass is an important topic for the research. Previous studies showed that broiler chickens have a fast growth rate during their early ages which is one of the main reasons for excessive body fat deposition. This situation is the most critical in broiler chickens that are reared with *ad-libitum* feeding, due to increase feed intake [Tumov & Teimouri, 2010]. However, feed re-

Table 1: Feeding schedule of treatments

Treatments	Day 8-14	Day 15-21
T1(Control)	<i>ad-libitum</i> feeding	<i>ad-libitum</i> feeding
T2	75% of <i>ad-libitum</i> feeding	<i>ad-libitum</i> feeding
T3	50% of <i>ad-libitum</i> feeding	<i>ad-libitum</i> feeding
T4	<i>ad-libitum</i> feeding	75% of <i>ad-libitum</i> feeding
T5	<i>ad-libitum</i> feeding	50% of <i>ad-libitum</i> feeding

The amount of feed which should be fed to birds in T2, T3, T4, and T5 was calculated based on the previous day feed intake of birds in control (T1) treatment.

restriction regimes have some success in increasing leanness in broilers [Choct *et al.*, 2005]. Nutritional studies have indicated that the various processes involved in adiposity can be altered by the level of feeding especially at an early age [Tumov & Teimouri, 2010]. Therefore, this study was conducted to evaluate the early quantitative feed restriction on the growth performance, meat quality, abdominal fat and serum lipid profile in the broiler chickens.

Methods

Experiment Location

Field work and laboratory analysis were conducted at Livestock farm and Animal and Food Science laboratory in Faculty of Agriculture, Rajarata University of Sri Lanka, Puliyankulama, Anuradhapura, from 5th February to 15th August 2018 respectively.

Broiler Management Practices

In the week prior to arrival of chicks, poultry house was cleaned. Brooder guards, feeders and waterers were thoroughly cleaned in the previous day and a foot bath was prepared. Day old broiler chicks were purchased from a commercial hatchery and transported to the experimental location. After arrival, they were weighed and provided glucose solution (Vitaguard) with drinking water to protect them from stress. Then, they were randomly introduced into two brooders of one hundred chicks per each and reared under good hygienic conditions. During this period, chicks had free access to water and feed. Electric bulbs (100 W) were used as the initial heating and lighting source for 24 hours of the day. Paddy husk was used as the litter material. Chicks were spent seven days

of brooding period. All chicks were provided with multi-vitamins (Bio-Vitamins Oral and Selvite-E) and Antibiotic (Enrocip) to avoid the risk of diseases during brooding. All birds were vaccinated against infectious bursal disease (IBD) at age of 7 and 14 days.

Birds and Experimental Design

A total of two hundred, Cobb 500 broiler chicks were used in the experiment. After 7 days of brooding period, they were randomly assigned to five treatments (Table 1) with four replicates per each treatment. Ten chicks were included in a replicate.

Broiler starter ration was fed from day 1 to day 21 and after 21 days of feeding, starter ration was gradually changed into the finisher which was continued until slaughtering. Nutritional composition of commercial feeds is presented in Table 2. During day 22 - 38, they were fed *ad-libitum*. Water was provided with *ad-libitum* and all other general management practices were followed until birds were slaughtered.

Slaughtering of Broilers

Three birds were randomly selected from each replicate at the 38th day of age for slaughtering and they were fasted for 12 hours. Ante-mortem assessments were done by visual observations and body weights of birds were recorded. Birds were held in killing cones and major blood vessels (carotid arteries and jugular veins) were cut within 10 seconds and kept for bleeding at least for 2 minutes. Slaughtered birds were scalded in hot water at the temperature of 56 °C for 2 - 5 minutes. The defeathering machine was used to remove the feathers and remained feathers were shaved. Then, a cut was made at the end of the abdomen and abdominal cavity was opened and the digestive tract,

Table 2: Nutritional composition of the commercial feeds

Nutrients	Starter	Finisher
Protein (%)	22	20
Fat (%)	6	7
Ash (%)	7	7.5
Fiber (%)	4.5	4.5
Calcium (%)	9.5 - 1.2	0.9 - 1.2
Phosphorous (%)	0.7 - 1	0.7 - 1
Metabolizable Energy (kcal / kg)	3000	3100

respiratory tract, and heart were removed. After proper cleaning, liver, heart, and gizzard were collected as giblets.

Data Collection and Calculations

Given feed quantity and remaining quantity were measured daily and then feed intake was calculated throughout the experimental period. Body weight was measured weekly, per pen basis and weight gain was calculated. Feed conversion ratio (FCR) was also calculated. Live weight at slaughtering and carcass weights were recorded and dressing percentage was calculated. The weights of body parts (breast, legs, and wings) were taken and expressed as a percentage of the carcass weight. Giblet weights (heart, liver, gizzard, and neck) were also recorded. Weights of abdominal fat pads were also measured.

The feed costs of starter and finisher rations throughout the study period were recorded. Feed cost per kg of live weight and feed cost per salable carcass were calculated.

Sample Collection and Analysis

After slaughtering, meat samples were taken from the breast area of birds and dry matter, crude fat, crude protein, total ash, crude fiber contents were determined [AOAC, 2003].

Blood samples were properly collected to sterilize tubes (without anticoagulant) at slaughtering from three randomly selected birds representing each replicate. Serum was immediately separated by centrifugation at 1500 rpm for 20 min (Labnet Int-C406490, USA). Then, samples were stored in -20 °C until further analysis. The serum samples were tested for total cholesterol, high den-

sity lipoproteins (HDL), triglycerides (TAG) and low density lipoproteins (LDL) using a commercial kit (BIOLABO, France) as per the manufacturers guidelines using a spectrophotometer (LABOMED, USA).

Data Analysis

Experiment was conducted in a completely randomized design (CRD). Statistical analyses were done using one-way Analysis of Variance (ANOVA) procedure in Statistical Analysis Software, version 9.0 [SAS, 2002]. Mean separation was done by Turkey's Standardized Range Test (TSRT). Statistical significance was declared at $p < 0.05$.

Results and Discussion

Growth Performances

Effect of each treatment on feed intake, weight gain and feed conversion ratio (FCR) during the experimental period are presented in Table 3. There were significant differences ($p < 0.05$) in feed intake among different treatments during day 8 - 21. The lowest feed intake was reported in the birds fed with 50% restricted diet during day 8 - 14 and day 15 - 21. The significantly ($p < 0.05$) highest intake was observed in the birds allotted in control treatment compared to the other treatments. Mahmood *et al.* (2007) reported similar results and birds reared under restricted feeding in second, and third weeks of age consumed lower amount of feed compared to the *ad-libitum* feeding. Novele *et al.* (2009) observed lower feed intake in 50% feed restricted birds compared to 25% restricted and *ad-libitum* fed birds at age of 21 days.

However, there were no any differences ($p > 0.05$) in feed intake among the treatments during the fin-

Day 8-38	1.53	1.5	1.44	1.45	1.4	0.1867	0.04

a, b, c, d means within the same row with different superscripts are significantly different ($p < 0.05$).

*Control= *ad-libitum* feeding, 75% @ day 8 - 14 = Provide 75% of *ad-libitum* feeding from day 8 - 14 of age, 50% @ day 8 - 14 = Provide 50% of *ad-libitum* feeding from day 8 - 14 of age, 75% @ day 15 - 21 = Provide 75% of *ad-libitum* feeding from day 15 - 21 of age, 50% @ day 15 - 21 = Provide 50% of *ad-libitum* feeding from day 15 - 21 of age.

isher period (day 22 - 38). Further, when total feed intake (from day 8 - 38) was considered, feed intakes were similar among *ad-libitum* feeding group and 25% feed restricted birds. However, the feed intake of 50% feed restricted groups were significantly lower ($p < 0.05$) compared to the *ad-libitum* fed group. These findings were in agreement with Plavnik & Hurwitz (1988) who reported reduced feed intakes with feed restriction without considering the age.

As the result indicated in table 3, the significantly highest ($p < 0.05$) body weight gain was ob-

served in the control group compared to the other treatments during day 8 - 21. Santoso (2001) observed similar results in body weight gain of birds fed *ad-libitum* as compared to the restricted feeding birds at the end of restriction period of 3 - 9 days. However, during the finisher period, birds allotted in control treatment showed the lowest ($p < 0.05$) weight gain while the highest gain was observed in 50% feed restricted group and the birds fed with 25% restricted diet in the 3rd week. However, when considered the total experimental period, there were no any differences ($p > 0.05$) in weight gain

^{a, b} means within the same row with different superscripts are significantly different ($p < 0.05$).

*Control = *ad-libitum* feeding, 75% @ day 8 - 14 = Provide 75% of *ad-libitum* feeding from day 8 - 14 of age, 50% @ day 8 - 14 = Provide 50% of *ad-libitum* feeding from day 8 - 14 of age, 75% @ day 15 - 21 = Provide 75% of *ad-libitum* feeding from day 15 - 21 of age, 50% @ day 15 - 21 = Provide 50% of *ad-libitum* feeding from day 15 - 21 of age.

among the treatments. The probable explanation for this consequence in the present study that, the compensatory growth might have occurred when restricted birds were re-fed *ad-libitum* after early restriction period. These results were in agreement with the previous findings of Santoso (2001), Santoso *et al.* (1995), Novele *et al.* (2009) and Plavnik & Hurwitz (1988, 1989). Dozier *et al.* (2002) also reported similar findings and the feed-restricted broilers gained greater body weight than *ad-libitum* feeding during their re-alimentation period.

During the day 8 - 21, FCR of birds in different treatments was not significantly different ($p > 0.05$) (Table 3). Previous studies also reported similar findings in the starter period [Mohebodini *et al.*, 2009]. However, birds in the control group reported the highest ($p < 0.05$) FCR in the finisher period and it did not differ from birds allotted in 25% feed restricted groups. The

significantly lower ($p < 0.05$) FCR values were observed in the 50% feed restricted groups compared to the *ad-libitum* fed group during the finisher period. However, when considered the total study period, FCR values did not differ ($p > 0.05$) among the birds in different treatments. It proved that the feed-restricted broilers attained improvement in feed conversion after the feed restriction and that was in agreement with the findings of Deaton (1995), Plavnik & Hurwitz (1988) and Zubair & Lesson (1996). The study of Yu *et al.* (1990) reported feed efficiency reduced for the restricted chicks in the first week after resuming *ad-libitum* feeding, but later it was slightly improved beyond the feed efficiency for the unrestricted chicks. However, the effect of feed restriction has yielded inconsistency findings in the literature. For example, Santoso (2001) reported the level or duration of feed restriction had no effect on FCR. On the other hand, Mahmood *et al.* (2007) reported that the

^{a, b} means within the same raw with different superscripts are significantly different ($p < 0.05$).

*Control = *ad-libitum* feeding, 75% @ day 8 - 14 = Provide 75% of *ad-libitum* feeding from day 8 - 14 of age, 50% @ day 8 - 14 = Provide 50% of *ad-libitum* feeding from day 8 - 14 of age, 75% @ day 15 - 21 = Provide 75% of *ad-libitum* feeding from day 15 - 21 of age, 50% @ day 15 - 21 = Provide 50% of *ad-libitum* feeding from day 15 - 21 of age.

birds reared under different feed restriction regimes utilized their feed more efficiently than those who fed with *ad-libitum*. Variations in results may be attributable to differences in feeding regimens practiced in different studies.

Carcass Characteristics of Broilers

According to Table 4, the differences were not significant ($p > 0.05$) for live weight, carcass weight and dressing percentage at 38th day of age among the treatments. Therefore, these findings indicated that complete compensation occurs in broilers during their re-feeding period after feed restriction. Lee & Lesson (2001) suggested that there are no losses of meat yield if birds are able to attain compensatory growth during their re-alimentation pe-

riod after feed restriction.

However, there was a significant difference ($p < 0.05$) in abdominal fat weight among the treatments. The back fat weight was significantly ($p < 0.05$) higher in birds fed *ad-libitum* compared to the feed-restricted group at their 2nd week of age. However, fat contents were similar in the *ad-libitum* fed birds and birds fed restricted feeds at their 3rd week of age. Hence, feed restriction at the day 8 - 14 age influenced the abdominal fat deposition in broilers. Santoso (2001) reported the similar findings and they observed a significant reduction in abdominal fat percentage and accumulation of fat in the body at the market weight when birds fed with 25% of *ad-libitum* for 9 days starting on

Table 6: Serum lipid profile of broilers fed in different feed restriction regime

**TCH = Total cholesterol, TAG = Triglycerides, HDL = High density lipoprotein, LDL = Low density lipoprotein.

Table 7: Feed cost analysis on the basis of live and salable weight

Cost (LKR)	Treatments*				P value	SE	
	Control	Day 8-14		Day 15-21			
		75%	50%	75%			50%
Feed cost/ 1 kg of live weight	142.00	139.00	136.00	135.00	131.00	0.4284	4.0
Feed cost/ 1 kg of salable weight	189.00	178.00	178.00	175.00	172.00	0.3655	6.0

Control = *ad-libitum* feeding, 75% @ day 8 - 14 = Provide 75% of *ad-libitum* feeding from day 8 - 14 of age, 50% @ day 8 - 14 = Provide 50% of *ad-libitum* feeding from day 8 - 14 of age, 75% @ day 15 - 21 = Provide 75% of *ad-libitum* feeding from day 15 - 21 of age, 50% @ day 15 - 21 = Provide 50% of *ad-libitum* feeding from day 15 - 21 of age.

the first day of the 2nd week of age. Further, Santoso *et al.* (1993) suggested that quantitative feed restriction reduced the fat deposition by inhibiting the activity of the rate-limiting enzyme during lipogenesis in the liver of chickens. These findings are also in agreement with the findings of Yang *et al.* (2010).

There were no any significant differences ($p>0.05$) among treatments in breast, leg, wings, liver, heart, gizzard and neck weights as a percentage of carcass weight. Mahmood *et al.* (2007), Mahmood *et al.* (2005) and Azahan (1984) also reported similar relative weights of heart, liver, spleen, gizzard, pancreas, and intestine in feed restricted and *ad-libitum* fed birds. Further, these findings were in accordance with the findings reported by Mahmood *et al.* (2007), Mahmood *et al.* (2005) and Azahan (1984). Moreover, Novele *et al.* (2009) determined the effect of different feed restriction regimes during the 15 - 21 days of age and reported that, the level of feed restriction and the sex of the chicken had no effect on breast, thigh, drumstick, wing, gizzard and liver weights when expressed as percentage of carcass weight at 42 days of age.

Meat Quality Parameters

According to the proximate composition, there was no any significant ($p>0.05$) difference in dry matter, ash, protein and fiber contents of meat samples among the treatments. However, muscle fat content was significantly higher ($p<0.05$) in birds fed *ad-libitum* compared to the birds which fed restricted diet in their 2nd week of age. However, the muscle fat contents were similar among the birds in control treatment and feed restricted groups in the 3rd week of age. Therefore, feed restriction in 8 - 14 days of age had the significant

effect on fat composition in chicken. Santoso (2001) showed that there was no effect in feed restriction on moisture and protein contents in chickens, but fat contents greatly reduced in feed restricted broilers compared to full fed broilers. Further, Zhan *et al.* (2007) and Omosebi *et al.* (2014) reported that fat content was lower whereas crude protein content was higher in feed restricted chickens than *ad-libitum* fed chicken. Moreover, Giachetto *et al.* (2003) indicated that there is no restriction effect on broiler carcass protein and total fat content. These discrepancies observed in literature may be due to the variation in feeding regime as well as the different levels and duration of feed restriction within the experiment.

Blood Serum Parameters

As per the table 6, there were no any significant differences ($p>0.05$) in total cholesterol, triglyceride, high-density lipoprotein (HDL) and low-density lipoprotein (LDL) levels in serum of birds in different treatments. At slaughtering, similar feed intake and growth performances were observed in each treatment. Therefore, it can be assumed that their metabolic processes were closely related to each other. Similar findings were observed by Alaquil & Zulkifli (2009) and showed that the effects of feeding regime on serum levels of cholesterol, glucose, potassium, and chloride were not different in broilers. On the other hand, Dawood (2015) reported that, the total plasma lipids, triacylglycerol, cholesterol, HDL were lower in the feed-restricted chickens, especially during the later phase of the experiment. Santoso (2001) also stated that serum triglycerides were significantly lower whereas cholesterol content was not significantly different in chicks reared in *ad-libitum* compared to restrict feeding. Mohebodini *et al.* (2009) and

Zhan *et al.* (2007) reported that serum triglyceride concentration has reduced in broilers at the end of the experiment.

Feed Cost Analysis

As per the table 7, there was no any significant difference ($p > 0.05$) among the treatments on the cost spent for feeds to produce 1 kg of live weight and salable weight. However, the highest and lowest feed cost to produce 1 kg of live weight and salable weight were observed in birds fed with *ad-libitum* and 50% feed restriction in the 3rd week of age, respectively.

Conclusions

Fifty percent feed restriction during day 8 - 14 reduces the feed intake of birds without affecting the weight gain, feed conversion ratio or dressing percentage compared to the birds fed *ad-libitum*. Further, abdominal and muscle crude fat contents in birds fed with restricted diets from day 8 - 14 reduce compared to the *ad-libitum* fed birds. A lower feed cost to produce 1 kg of live and salable weight is also observed in birds fed with 50% feed restriction in the 2nd week of age compared to the birds fed with *ad-libitum*. Hence, 50% feed restriction during day 8 - 14 reduces the fat deposition without interfering on growth performances in broiler chicken with lower cost.
